PROJECT REPORT

My dataset contains 137057 observations of 17 data-related variables in a hospital environment. I stress certain factors that are prone to data analysis; those are as follows:

- Hospital Region
- Admission Type
- Department
- Ward Type
- Bed Grade
- Severity of Illness
- Age
- Admission Deposit

To critically evaluate the data with logical thought, I used R programming we learned very recently. I believe this analysis helps me implement my knowledge of R programming to execute a project effectively and efficiently. I have downloaded this dataset from the renowned data analysis repositior Kaggle website advised by our instructor.

In terms of data analysis, we can easily note the relationship between certain variables and the effect at first glance. For example, when it comes to various types of diseases in the given dataset, individuals in the age group of 41-50 are getting more attention. I also show that, relative to other hospitals, more patients are admitted by hospitals in the "X" region. Apart from this, Ward "R" offer more facilities for patients with Trauma compared to other wards in the hospital. In the same way, the hospital's gynaecology department is the busiest in terms of treating more patients than other units. I could not find any significant difference when it comes to "Bed Grade". However, relative to the rest of the age group, the youngest and oldest patients put up more deposits.
